(Received: 13 November 2019; accepted: 27 December 2019)

Isoprinosineis a combination of inosine used as antiviral drug without effect on viral particle itself, but instead only and acts as on immunostimulant and also acts indirectly by activation of immune cells. Aim of this study was to determine level of interferon-alpha (INF-α) with paramyxoviruses HPIV-2, and adenoviruses HAdV-2 replication. In the present study, cytotoxic effect of isoprinosine was assessed using A549 cell line exposed to different concentrations of compound (isoprinosine: 50-800μg/mL) for 48 hours. Cytotoxic effect was examined visually using light, inverted microscopy Olympus CK2 under 400x magnification and by the MTT colorimetric assay. The yield reduction assay (YRA), which evaluates the ability of the isoprinosine(50-800 μg/mL) to inhibit virus multiplication in cell cultures, was applied. The cytopathic effect of the virus was evaluated 48 h after infection of A549 cell cultures with viruses by means of light, inverted microscopy. The YRA method was used to determine the 50% end point (IC50) in the presence of Isoprinosine with the controlled one. MTT cytotoxicity assay confirmed microscopic observations.There were no morphological changes, as assessed visually, in cell cultures treated with isoprinosine. After conducting the experiments and analyzing the results we noticed that higher concentrations of isoprinosine strongly inhibited multiplication of all viruses. HPIV-2 and HAdV-2 showed the highest sensitivity to the antiviral activity of isoprinosine as compared with the control, however, increasing concentrations of isoprinosineup to 800 μg /ml slightly enhanced the antiviral activity of 400 μg/ml isoprinosine. Our study was conducted that HAdV-2 and HPIV-2 have the highest sensitivity to the antiviral activity of isoprinosine from all tested viral strains.

Keywords: Adenoviruses, antiviral activity, Isoprinosine, parainfluenza viruses.
specific ones receptors for cells and analysis based on antiviral proteins. Viral dsRNA is an inducer of IFN-α production. In infected cells antiviral effect of interferon generated with enzyme activity: 2', 5'-oligoadenyl synthetase and protein kinase R (PKR), resulting in inhibition of synthesis proteins by PKR phosphorylation and degradation of viral. IFN-α stimulates also cellular response by activating effector cards. Stimulates for example, pre-NK cells for differentiation into NK cells and activates early, natural protection against infection. INF-α together with IFN-α increase expression MHC class I molecules, which improves the ability of the cell to present antigen. State antiviral, stimulated by the presence of IFN-α in the infected cell, lasts about 2-3 days. Despite the fact that about 60 antiviral drugs are currently available, close half of them are registered for the treatment of HIV infection. Others are used in the treatment of viral hepatitis (HBV, HCV), human infection herpesviruses and influenza viruses. There is still a lack of possibilities to control many important ones clinically and epidemiologically viral infections. Infections caused by adenoviruses or parainfluenza viruses are common, usually mild, self-limiting infections. However, the immune system can cause serious complications. Adenoviruses initially infect or reactivate in 20-50% of people with immunosuppression, causing organ or generalized infections. Parainfluenza viruses in situations of weakened immune mechanisms the body cause acute pneumonia, requiring artificial ventilation and in part cases (5-35%) resulting in death. None of the previously known preparations antiviral has no registration for the treatment of infections with these viruses. Isoprinosine is a complex of inosine, p-acetamidobenzoate and diamidopropanol - a drug belonging to the group of general purpose antiviral pharmaceuticals. Isoprinosine except antiviral activity has confirmed in both in vitro and in clinical trials, an immunomodulatory effect. It is likely that this compound is involved in inhibition viral RNA synthesis. Stimulates the immune system affecting puberty as well as the inhibition of lymphocytes. Numerous studies (in vitro and in vivo) have shown to increase Isoprinosine production of cytokines such as interleukin (IL-1, IL-2 and IL-12), interferon α (IFN-α), TNF-α, and interferon α (IFN-α), inhibits IL-10 production, enhances the effect of cytotoxic (natural killer; NK cells) and stimulates chemotaxis and phagocytosis. The aim of the study was to assess the effect of interferon-α and Isoprinosine in titers infectious RNA viruses: parainfluenza virus (human parainfluenza 2 virus; HPIV-2) and human adenovirus (human adenovirus 2; HAdV-2) in vitro.

**MATERIAL AND METHODS**

RNA viruses pathogenic to humans were used in the study: adenovirus 2 (HAdV-2) and parainfluenza virus type 2 (HPIV-2). Viruses propagated in A549 cell line (ATCC® CCL-185MT). Cells were cultured in medium Dulbecco’s Modified Eagle’s Medium (DMEM, ThermoFisher Scientific) supplemented with 10% calf fetal bovine serum (FBS; ThermoFisher Scientific) and a 1% penicillin / streptomycin and antimicotic solution (BI; Biological Industries) and 5% atmosphere. For reproduction viruses, and evaluation of antiviral activity, reduced fluid medium was used up to 2% FBS concentration. Interferon-α (Switzerland) was added to the culture at concentrations of 100 and 1000 IU/ml. Interferon doses were selected based on literature analysis and own experience. Isoprinosine (BI; Biological Industries) in a dose 5.0 mg were suspended in 5.0 mL of Phosphate-buffered saline (PBS, PH=6.9), filtered using a millipore filter (Filter Unit, 0.2 μm). Prepared non-toxic for cell culture concentration: 50-800 μg / ml. The selection of doses was determined on the basis of previously conducted and published research results, in which using the method qualitative using an inverted optical microscope (OLYMPUS), image enlarge by 400x and by quantitative method using the tetrazole salt reduction test in cell mitochondria, MTT Cell Proliferation Assay (ATCC bioproducts ™, USA) has been shown to be non-toxic isoprinosine activity on A549 culture, HEP-2 and HEL 299 cell lines. Antiviral activity testing involved infection of A549 cells (1x105 cells / ml) with each virus at a dose of 100 TCID50 / ml (Tissue Culture Infectious Dose). After 60 min incubation of the virus with cells in micro plates (in a volume of 0.2 ml in flat-bottom 96-well plates, (MEDLAB-PRODUCTS) twice cultures were washed with PBS to remove non-cell-associated viruses. Then, infected cells were added:
1. D-MEM medium (virus control).
2. Isoprinosine at concentrations from 50 to 800 ìg / ml in DMEM liquid medium.
3. IFN-á at a concentration of 100 or 1000 IU / ml.
4. Isoprinosine and IFN-á in w/w concentrations.

The exposure time in each system was 48 hours the antiviral effect was determined by the method of reduction of infectious titers (YRA – yield reduction assay). The virus infectious titer is expressed in log_{10} TCID_{50} / ml. Significance was determined differences between average virus titers, cell culture microplates were frozen and thawed three times(to release viruses from cells), centrifuged for 10 minutes (3000 rpm, temperature 4 °C). The supernatant was used to assess viral load according to the Reed-Muench method.

**Statistical analysis**

Student’s t-test was used for related variables, the significance level P <0.05 was adopted. The results were statistically evaluated using the Pearson correlation method measuring the relationship between isoprinosine doses and viral load and INF-á. Correlation coefficient value in the range of 0.4-0.7 interpreted as a moderate relationship, 0.7-0.9 relationship significant above 0.9 as a very strong relationship.

**RESULTS**

There was no toxicity to Isoprinosine at concentrations between 50 and 800ìg / ml for culturing. IFN-á has been shown to significantly inhibit the multiplication of these viruses in research in vitro (P <0.05). The reduction of infectious titers was linearly dependent on concentration IFN-á. The concentration of 100 IU / ml, 1000IU / ml andisoprinosine in concentrations 200ìg / ml and 800ìg / ml. IFN-á reduced the infectious titre HPIV-2, and HAdV-2 respectively by more strongly inhibited replication resulting in 100 IU / ml, 1000IU / ml and isoprinosine in concentrations 50ìg / ml, 100ìg / ml and 400ìg / ml compared with a control. Analyzing the Pearson correlation coefficient was demonstrated significant (P <0.05) dependence of the infectious titre HPIV-2 and HAdV-2on the dose of isoprinosine in cultures A549.

Similarly, a high correlation coefficient (however not statistically significant) was calculated for other RNA viruses: HPIV-2 and HAdV-2. Isoprinosine most significantly reduced HAdV-2 infectious titers compared to control, but increased isoprinosine concentrations up to 800 ìg / ml slightly enhanced the antiviral effect of 50 ìg / ml isoprinosine. As shows table (1) In vitro experiments have shown that isoprinosine even more strongly reduces infectious adenovirus titers in the presence of interferon-á (IFN-á). Simultaneously the addition of 100 IU / mL and 1000 IU / mL IFN-á and isoprinosine to A549 infected cells with resulted reduction of IC_{50} values (media concentration of the inhibitor that inhibits infectious titers by 50%) from 9051ìg / mL to 8931ìg / mL for HPIV-2 respectively, 9873.75ìg / mL for HAdV-2.

DISCUSSION

Isoprinosine has antiviral activity, it also has confirmed immunomodulatory effect\(^\text{14}\). Its effectiveness has been described in randomized and double-blind clinical trials. Derouët analyzing the results Ginsberg et al\(^\text{15}\), experiments confirm good drug tolerance in the macroorganism. After reaching a high concentration in tissues, isoprinosine is metabolized to uric acid and completely eliminated by the kidneys\(^\text{16}\). The study showed that Isoprinosine is not cytotoxic to A549 cells. Isoprinosine at a dose of 800 \(\mu\)g / mL also does not change the morphology and does not affect biological activity (in the MTT test) HEP-2 and HEL 299 cell lines\(^\text{17}\). Assessing the effect of isoprinosine on the replication of parainfluenza and adenoviruses has been shown to isoprinosine after 48 hours. Adenoviruses (HAdV-2) have also been shown to be of the highest susceptibility to the antiviral effect of Isoprinosine among all used in the study of virus strains. In vitro experiments have shown that isoprinosine even more strongly reduces infectious adenovirus titers in the presence of interferon-\(\alpha\) (IFN-\(\alpha\)). Simultaneous addition of 100 IU / mL and 100 IU / mL IFN-\(\alpha\) and isoprinosine to A549 infected cells with resulted reduction of IC\(_{50}\) values (media concentration of the inhibitor that inhibits infectious titers by 50%) from 9051 \(\mu\)g / mL to 8931 \(\mu\)g / mL for HPIV-2 respectively, 9873.75 \(\mu\)g / mL to 7816.5 \(\mu\)g / mL and HAdV-2, respectively. Enhancement of the action of Isoprinosine in the presence of INF-\(\alpha\) has been demonstrated also towards the reference strain (Human Herpesvirus1) HHV-1 McIntyre strain\(^\text{19}\). It also turns out to be simultaneous administration of IFN-\(\alpha\) and isoprinosine results in improvement of the neurological condition of patients with subacute sclerosing encephalitis (a complication after mumps infection) and helps conventional treatments for local human papillomavirus infection in infected persons herpes simplex viruses, as well as hepatitis A\(^\text{26}\). Ochocka et al.\(^\text{200627}\) describe good isoprinosine tolerance and reduction of illness time due to human alpha herpesvirus infection in children with acute lymphoblastic leukemia treated with isoprinosine. Positive pharmacological effect of isoprinosine has also been demonstrated in the treatment of symptomatic human papillomavirus infection in women\(^\text{28}\). In a study conducted by Rhoades et al.,\(^\text{29}\) isoprinosine was shown to influence the dynamics of HIV infection; reduces the level of reverse transcriptase and reduces expression p24 and gp120 on the surface of HIV infected lymphocytes. In addition, it was observed that viability, as well as the number of CD4 + cells and the ratio CD4 + / CD8 + are higher in culture.
cell treated with isoprinosine compared to HIV infected and non-exposed isoprinosine cells. In vitro studies have been observed antiviral activity of isoprinosine and inhibiting the multiplication of viruses as a result of the combined administration of isoprinosine and interferon-α. Isoprinosine and IFN-α have been shown to reduce infectious titers of DNA viruses such as human adenoviruses and herpes viruses common. In patients with subacute sclerosing encephalitis (SSPE), associated with measles virus infection, combination therapy is recommended isoprinosine with interferon, due to their likely synergistic actions. Currently, there is no possibility of fully effective causal treatment of infections caused by viruses used in the RNA study. It is also not available specific prevention. Therefore, when confirmed in vivo, demonstrated in an antiviral study of co-administered interferon and isoprinosine, it is possible to include such a combination in controlling infections viral.
